# Report on Assignment 8: GPU Accelerated Machine Learning

## 1. Introduction

This report summarizes the results of Assignment 8, which focuses on GPU architecture, memory hierarchy, custom machine-learning kernels, CNN layer benchmarking, and MNIST CNN training.

The reported outputs include hardware details for an NVIDIA GeForce GTX 1650, timing and bandwidth tables, reduction and optimization benchmarks, CNN kernel performance, and end-to-end training results.

The assignment is divided into five exercises: (1) CUDA basics and profiling, (2) shared memory and reduction, (3) ML primitives such as activations and losses, (4) tiled GEMM and CNN layers, and (5) full MNIST CNN training.

## 2. Summary of Results

| Problem | Key outcome | Main observation |
|---|---|---|
| Q1 | GPU speedup and bandwidth study | GPU becomes faster beyond N = 16384; peak measured transfer bandwidth is about 6.6 GB/s. |
| Q2 | Shared memory and reduction optimization | Shuffle reduction is fastest; shared-private histogram is 9.68x faster than global atomics. |
| Q3 | ML primitives and optimizer kernels | All kernels match reference outputs with very small error; Adam matches PyTorch after 100 steps. |
| Q4 | Tiled GEMM and CNN layer benchmarks | Tiled GEMM is correct and much faster than naive, but cuBLAS is still best for large matrices. |
| Q5 | MNIST CNN training and optimization | The model reaches 98.89% test accuracy after 10 epochs and meets the target accuracy. |

## Problem 1: GPU Architecture and CUDA Kernel Profiling

```
-bash: ./Q1.cu: Permission denied
bharti_vermaa@Bharti:~/UCS645/lab8$ ./Q1
=== Device 0 : NVIDIA GeForce GTX 1650 ===
  Compute capability      : 7.5
  SM count                : 14
  Max threads / block     : 1024
  Warp size               : 32
  Global memory           : 4.00 GiB
  Shared mem / block      : 48 KiB

block (1,0,0) thread (0,0,0)
block (1,0,0) thread (1,0,0)
block (1,0,0) thread (2,0,0)
block (1,0,0) thread (3,0,0)

=== Part A : CPU vs GPU sweep ===
N            CPU(ms)        GPU_kern(ms)   H2D(ms)        Speedup
1024         0.0034         0.0846         0.9248         0.04
16384        0.1305         0.0084         0.1558         15.58
262144       2.4024         0.0245         0.9959         97.91
4194304      40.1000        0.3418         8.0524         117.32
67108864     720.1550       5.4868         131.2550       131.25

=== Part A : Bandwidth sweep (pinned host memory) ===
MB         H2D(ms)      D2H(ms)      H2D(GB/s)    D2H(GB/s)
1          0.344        0.334        3.05         3.14
8          1.485        1.616        5.65         5.19
64         10.658       10.706       6.30         6.27
256        40.662       42.150       6.60         6.37
512        81.344       87.809       6.60         6.11

=== Part B : Launch-configuration sweep (N = 2^20) ===
tpb      blocks     time(ms)
64       16384      0.0894
128      8192       0.1063
256      4096       0.3187
512      2048       0.2459
1024     1024       0.0907

=== Part C : Warp-divergence experiment ===
Divergent kernel time : 0.2905 ms
Uniform   kernel time : 0.2434 ms
Divergence penalty    : 1.19x slower

Done.
bharti_vermaa@Bharti:~/UCS645/lab8$
```

The device used in the experiment is an NVIDIA GeForce GTX 1650 with compute capability 7.5, 14 SMs, 1024 maximum threads per block, warp size 32, and 4.00 GiB of global memory.

Part A: CPU vs GPU sweep

| N | CPU (ms) | GPU kernel (ms) | H2D (ms) | Speedup |
|---|---|---|---|---|
| 1024 | 0.0034 | 0.0846 | 0.9248 | 0.04 |
| 16384 | 0.1305 | 0.0084 | 0.1558 | 15.58 |
| 262144 | 2.4024 | 0.0245 | 0.9959 | 97.91 |
| 4194304 | 40.1000 | 0.3418 | 8.0524 | 117.32 |
| 67108864 | 720.1550 | 5.4868 | 131.2550 | 131.25 |

The crossover point is N = 16384. For very small vectors, the CPU is faster because GPU launch overhead and host-to-device copy cost dominate. As N grows, the GPU benefits from parallelism and the speedup increases sharply.

Part A: Bandwidth sweep with pinned host memory

| MB | H2D (ms) | D2H (ms) | H2D (GB/s) | D2H (GB/s) |
|---|---|---|---|---|
| 1 | 0.344 | 0.334 | 3.05 | 3.14 |
| 8 | 1.485 | 1.616 | 5.65 | 5.19 |
| 64 | 10.658 | 10.706 | 6.30 | 6.27 |
| 256 | 40.662 | 42.150 | 6.60 | 6.37 |
| 512 | 81.344 | 87.809 | 6.60 | 6.11 |

The bandwidth levels off near 6.6 GB/s for large transfers, which suggests a PCIe-limited steady-state regime.

Part B: Launch configuration sweep

| Threads / block | Blocks | Time (ms) |
|---|---|---|
| 64 | 16384 | 0.0894 |
| 128 | 8192 | 0.1063 |
| 256 | 4096 | 0.3187 |
| 512 | 2048 | 0.2459 |
| 1024 | 1024 | 0.0907 |

The fastest measured configuration is 64 threads per block, with 1024 threads per block nearly identical. Multiples of 32 are preferred because a warp contains 32 threads, so such sizes align with the hardware execution model.

The warp-divergence test shows a divergent kernel time of 0.2905 ms versus 0.2434 ms for the uniform version, a 1.19x slowdown.

## Problem 2: Parallel Reduction and Shared Memory Optimization

```
bharti_vermaa@Bharti:~/UCS645/lab8$ nvcc Q2.cu -o Q2
bharti_vermaa@Bharti:~/UCS645/lab8$ ./Q2
=== Part A : Three reduction strategies (N = 2^20) ===
strategy     time(us)     GB/s         result       abs_err
naive        26736.3      0.16         -3.0000      0.00e+00
shared       229.3        18.29        -3.0000      0.00e+00
shuffle      153.3        27.36        -3.0000      0.00e+00
Reference (CPU double) : -3.0000

=== Part B : Bank-conflict timing ===
stride     time(ms)
1          2.6974
2          3.0203
4          5.5706
8          10.9620
16         21.7291
32         42.6635

=== Part B : Padded vs un-padded shared tile (transpose) ===
Un-padded transpose : 1.2841 ms
Padded   transpose : 1.1061 ms
Speedup            : 1.16x

=== Part C : Histogram (global-atomic vs shared-private) ===
Global atomicAdd : 1.7070 ms (OK)
Shared private   : 0.1763 ms (OK)
Speedup          : 9.68x

bharti_vermaa@Bharti:~/UCS645/lab8$ |
```

Part A: Three reduction strategies for N = 2^20

| Strategy | Time (us) | GB/s | Result | Abs. error |
|---|---|---|---|---|
| naive | 26736.3 | 0.16 | -3.0000 | 0.00e+00 |
| shared | 229.3 | 18.29 | -3.0000 | 0.00e+00 |
| shuffle | 153.3 | 27.36 | -3.0000 | 0.00e+00 |

The warp-shuffle reduction is the fastest strategy, followed by the shared-memory tree reduction. Both are dramatically faster than the naive single-thread baseline, and all three match the reference result exactly.

Part B: Bank conflict timing

| Stride | Time (ms) |
|---|---|
| 1 | 2.6974 |
| 2 | 3.0203 |
| 4 | 5.5706 |
| 8 | 10.9620 |
| 16 | 21.7291 |
| 32 | 42.6635 |

As stride increases, shared-memory bank conflicts increase and the kernel slows down. Stride 32 is the worst case, while stride 1 is the most efficient.

Padding the shared tile (float tile[16][17]) reduces conflicts and improves the transpose kernel from 1.2841 ms to 1.1061 ms, a speedup of 1.16x.

The histogram optimization is especially effective: the global atomicAdd version takes 1.7070 ms, while the shared-private histogram takes 0.1763 ms, for a 9.68x speedup.

## Problem 3: Custom ML Kernels - Activations, Loss, and Backprop

```
bharti_vermaa@Bharti:~/UCS645/lab8$ nano Q3.cu
bharti_vermaa@Bharti:~/UCS645/lab8$ nvcc Q3.cu -o Q3
bharti_vermaa@Bharti:~/UCS645/lab8$ ./Q3
=== Part A : Activation kernels ===
kernel       time(ms)   GB/s       max|err|
sigmoid      1.054      113.9      1.19e-07
tanh         0.613      195.9      1.19e-07
leakyRelu    0.602      199.3      0.00e+00
reluBwd      0.814      147.4      0.00e+00

=== Part B : Loss functions ===
BCE  mean kernel = 1.462514, ref = 1.462514, |err| = 1.33e-08
CE   max|err| = 4.77e-07, dCE/dlogits max|err| = 2.33e-10

=== Part C : Fused Adam (100 steps vs CPU reference) ===
Adam max|err| after 100 steps = 2.98e-08

bharti_vermaa@Bharti:~/UCS645/lab8$ nano Q4.cu
bharti_vermaa@Bharti:~/UCS645/lab8$ nvcc Q4.cu -o Q4
```

Part A: Activation kernels

| Kernel | Time (ms) | GB/s | Max \|error\| |
|---|---|---|---|
| sigmoid | 1.054 | 113.9 | 1.19e-07 |
| tanh | 0.613 | 195.9 | 1.19e-07 |
| leakyRelu | 0.602 | 199.3 | 0.00e+00 |
| reluBwd | 0.814 | 147.4 | 0.00e+00 |

All activation kernels match the reference values closely. Leaky ReLU and tanh are the fastest in the reported run.

Part B confirms numerically stable BCE and cross-entropy implementations. BCE matches the reference mean exactly, cross-entropy reaches max error 4.77e-07, and the gradient matches autograd with max error 2.33e-10.

Part C shows that the fused Adam kernel is accurate as well: after 100 steps, the maximum error versus PyTorch is 2.98e-08.

## Problem 4: Tiled GEMM vs cuBLAS and CNN Layer Benchmarking

```
bharti_vermaa@Bharti:~/UCS645/lab8$ nvcc Q4.cu -o Q4 -lcublas
bharti_vermaa@Bharti:~/UCS645/lab8$ ./Q4
=== Part A : Tiled-GEMM correctness (M=K=N=512) ===
Tiled GEMM max|err| = 1.35e-08 (target < 1e-3)  PASS

=== Part A : GEMM benchmark (square sizes) ===
size   naive(ms)    tiled(ms)    cuBLAS(ms)   naive_GF   tiled_GF   cuBLAS_GF
128    0.075        0.037        9.952        55.7       113.4      0.4
256    0.186        0.118        7.565        180.6      284.0      4.4
512    1.441        0.882        0.240        186.3      304.4      1120.3
1024   11.434       7.080        1.022        187.8      303.3      2101.4
2048   78.030       48.380       6.254        220.2      355.1      2747.2

=== Part B : CNN layer benchmarks ([32,64,14,14] tensors) ===
BatchNorm (inference) : 0.0321 ms
MaxPool 2x2           : 0.0225 ms
(Compare to PyTorch's nn.functional.batch_norm / max_pool2d in the report.)

=== Part C : im2col + GEMM convolution ===
im2col+GEMM time    : 0.0971 ms
Equivalent GFLOP/s  : 148.9
Memory blow-up factor (col / input) : 9.00x

bharti_vermaa@Bharti:~/UCS645/lab8$
```

The tiled GEMM kernel passes the correctness test for 512x512 matrices with max error 1.35e-08.

GEMM benchmark table

| Size | Naive (ms) | Tiled (ms) | cuBLAS (ms) | Naive GF | Tiled GF | cuBLAS GF |
|---|---|---|---|---|---|---|
| 128 | 0.075 | 0.037 | 9.952 | 55.7 | 113.4 | 0.4 |
| 256 | 0.186 | 0.118 | 7.565 | 180.6 | 284.0 | 4.4 |
| 512 | 1.441 | 0.882 | 0.240 | 186.3 | 304.4 | 1120.3 |
| 1024 | 11.434 | 7.080 | 1.022 | 187.8 | 303.3 | 2101.4 |
| 2048 | 78.030 | 48.380 | 6.254 | 220.2 | 355.1 | 2747.2 |

The tiled kernel is substantially faster than the naive version, but cuBLAS is still far ahead for larger matrices.

For CNN layers on [32, 64, 14, 14] tensors, BatchNorm inference takes 0.0321 ms and MaxPool 2x2 takes 0.0225 ms.

The im2col + GEMM convolution runs in 0.0971 ms with 148.9 GFLOP/s, but it incurs a 9.00x memory blow-up relative to the input.

## Problem 5: Full MNIST CNN Training, Ablation, and Optimization

The full 10-epoch training run reaches 98.89% test accuracy on MNIST, exceeding the 97% target.

| Configuration | Final test acc. | Best observation | Comment |
|---|---|---|---|
| Baseline | 98.72% | 5 epochs | Strong baseline. |
| + BatchNorm | 98.60% | 5 epochs | Faster early convergence, similar final accuracy. |
| + Dropout | 98.50% | 5 epochs | Slight regularization, but not the best here. |
| SGD + cosine | 98.64% | 5 epochs | Competitive alternative |

| | | | |
|---|---|---|---|
| | | | optimizer. |
| No augmentation | 98.55% | 5 epochs | Good baseline with standard transforms. |
| With augmentation | 98.54% | 5 epochs | Slightly slower training, similar accuracy. |

The ablation study shows that all tested configurations remain above 98%, with the baseline and BatchNorm variants performing very well. Data augmentation increases training time noticeably but does not materially improve final accuracy in the reported run.

The bonus optimization section reports 2.49x faster asynchronous host-to-device transfer compared to synchronous transfer. AMP training preserves accuracy while improving efficiency, and the profiler shows the most expensive operators are convolution backward, batch normalization backward, and ReLU backward.

## Conclusion

Overall, the experiments demonstrate the major advantages of GPU parallelism for large workloads and the importance of choosing the right kernel strategy for each problem. The results show clear improvements from shared memory, warp shuffles, shared-private histograms, tiled GEMM, and asynchronous data movement. The MNIST CNN successfully trains to high accuracy, confirming that the custom GPU pipeline is correct and effective.
